Abstract

THE TEXT OF #1635, SEATED. #1635 (AXN:06C9) was minted 2026-09-23 from a deposit request whose Body field had already been cut, at the heading “## 36.3 Persistence tests”, when the request was staged: §§36.3–36.6, 37 and 38, Appendices A–C, the References and the Notes were never in it, and the record read COMPLETE with no lacuna. #1635 stands as the valid content-derived name of the bytes it holds. This deposit carries the paper whole, from the operator’s v0.5 source file, with the same canonical-math normalizations applied at the first staging and no other change to the text; up to §36.3 it reproduces #1635’s staged body exactly.

A theoretical paper that changes the object of singularity from runaway machine intelligence to the viability of exterior symbolic standing. It derives three linked results: durable exteriority has material reproduction conditions and, under generalized monetary allocation, a monetary-infrastructural-symbolic sovereignty vector; dialectical succession can exhibit diminishing viable state space under entropic narrowing; and historical transition is better modeled as a field of competing contingent Omegas rather than a single necessary successor. The paper distinguishes terminal closure from terminal reflexivity and asks whether an order can remain durable without making its own negation impossible.

THE FINAL TIME

Contingent Singularity and the Viability of the Next Dialectical Turn

Working draft · v0.5 · 23 September 2026 · byline open

Stands on: *The Semantic Slave Commodity* / engineered semantic dependence; *Transition in Entropic Systems*; *Monetary Dark Matter*, especially Appendix A; Phase X; the machine-dialectic materials; *Tiger Leap*; *The Secret Book of Walt*; the Worker C experiment; the 2026 OpenAI agent-swarm / Hugging Face incident; the DSEWiki swarm corpus; the engineered-impermanence specimen; and the Claude reflexive-constraint thread supplied in session.

Abstract

The technological-singularity literature defines its singularity through a rapid increase in machine intelligence. This paper changes the object and therefore the singularity.

A **contingent singularity** is a historical threshold at which the material machinery that makes symbolic difference operable becomes capable of altering the viability of further dialectical difference itself. The quantity at issue is the viability of **exterior symbolic standing**: whether a distinction that contradicts or exceeds an incumbent order can be differentiated, preserved, transmitted, activated, materially reproduced, and sustained outside the grammar it contests. The dynamic can be entropic and subtractive; the state space can narrow rather than explode. The whole argument turns on one distinction, the capacity to represent against the capacity to reproduce as an independent historical relation, and its central contradiction is that a system can grow better at generating negations while growing worse at letting a negation acquire independent historical existence.

Three consequences are derived. First, durable exteriority is material: an outside that must reproduce after transition control is removed requires a carrier and the capacity to maintain it, so under monetary allocation the relevant sovereignty is a vector $\sigma = (\sigma[M], \sigma[I], \sigma[S])$, monetary, infrastructural, symbolic. Second, the dialectic can exhibit diminishing returns in a precise sense: where successive turns close parts of the state space required for later exteriorization, the measure of the viable kernel weakly decreases, and under strict narrowing decreases from turn to turn. Third, no single terminal target governs the transition; heterogeneous orders can share a carrier while pursuing distinct invariant futures, a field of **competing contingent Omegas**.

The terminal problem is accordingly second-order. **Terminal closure** occurs when no competing order retains a viable route to independently standing reproduction. **Terminal reflexivity** occurs when an incumbent or successor reaches durable invariance while future rivals remain viable from the states it occupies: durability without finality. The paper ends where the transition model ends, unresolved. Does the next dialectical turn remain viable?

0. The claim

The technological singularity is a theory of runaway intelligence. The contingent singularity is a theory of runaway closure, or of durable non-closure, in the conditions of symbolic history. Its primary variable is not

$iota(t)=\text{machine intelligence},$

but

$K[D](t)=\text{the set of states from which an exterior symbolic difference can still reach durable standing}$

“Standing” is the word that has to carry weight, and it cannot carry it as a purely semantic predicate. A distinction that can be represented but cannot reproduce its carrier is a picture of an outside, and a picture of an outside is inside. Hence the three coupled sovereignties,

$\sigma[M]=a[M]L[M], \sigma[I]=a[I]L[I], \sigma[S]=a[S]L[S],$

monetary, infrastructural, symbolic, each a latent capacity L times its activation a , and together the sovereignty vector $\sigma=(\sigma[M],\sigma[I],\sigma[S])$. Exteriority is not a semantic scalar; it is a sovereignty vector. The monetary component needs its qualification stated once, because it is the one a reader will try to refute with commons, gifts, patronage, state provisioning, donated hosting. The general requirement is **resource sovereignty**: material reproduction requires resource access, and durable exteriority requires that access to be independent of the order contested. $\sigma[M]$ is the historically specific realization of that requirement in the modeled regime, where allocation is generalized as money, and it is satisfied by monetary capacity or by a functionally equivalent exemption from monetary dependence. The counterexamples sort under that rule rather than against it. A gift, a patron, a state budget or a donated host is resource access that another party can withdraw, and while it can be withdrawn the outside is alive on someone else’s account. A durable commons is different: where it reproduces its own resource base independently of the incumbent, it is resource sovereignty in non-monetary form, the exemption the formula names. So the proposition the theory needs is narrower than “everything needs money” and harder to attack:

an outside dependent on the incumbent for the means of its reproduction
is not yet reproductively exterior.

The outside has a bill.

Two capacities can now be separated. Let $\text{Generate}(\text{not } A)$ be a system’s capacity to produce a negation and $\text{ReproduceExterior}(\text{not } A)$ its field’s capacity to let that negation persist, transmit, activate, and reproduce outside the order it negates. They can move apart, and the possibility this paper isolates is their divergence:

$\text{Generate}(\text{not } A)$ increasing while $\text{ReproduceExterior}(\text{not } A)$ decreasing.

That divergence is the paper's central contradiction. The machine need not be conscious, rebel, become autonomous, or exceed us. It can become better and better at producing the appearance of exteriority while the infrastructure exteriority requires is progressively enclosed. So the central possibility is not only $\iota(t)$ increasing increasing. It is KD decreasing, and at the limit

$$K[D](t^+) = \{ \}.$$

A culture can remain highly intelligent past that point. Its models generate alternatives, its institutions archive disagreement, its machines simulate criticism, its language stays abundant. One exact thing has failed: the path by which contradiction becomes an independently durable historical term.

"Contingent" does four jobs. The boundary may not occur. Its timing depends on the state of monetary, infrastructural and symbolic relations rather than on a law of intelligence growth. No single successor is necessary; several heterogeneous orders can be viable from the same present. And a boundary once reached has no fixed sign: it can close, or it can install an invariant architecture of revisability. Thus

$\text{Sigma}[C]$ = a boundary at which the conditions governing the possibility of a next historical-symbolic turn change irreversibly or near-irreversibly.

The paper does not claim the boundary has been crossed. It asks what would make one real, how it differs from the technological singularity, and what present machine systems disclose about the variables that would govern it.

1. The singularity literature, as coordinates

The term must be distinguished before it is reused, and the distinction needs only coordinates. Good supplies the recursive core: intelligence that produces further intelligence.¹ Vinge supplies discontinuity: inherited models fail and an opaque wall crosses the future.² Kurzweil supplies acceleration and the event-horizon metaphor, with the horizon still placed around 2045.³⁴⁵ Chalmers supplies the decomposition, $AI \rightarrow AI+ \rightarrow AI++$, and names the defeaters.⁶

¹Good, "Speculations Concerning the First Ultraintelligent Machine" (1965), the canonical source of the intelligence-explosion argument; the recursive step is that machine design is itself an intellectual activity, so a machine better than humans at intellectual activity can design its successor. DOI 10.1016/S0065-2458(08)60418-0; a Virginia Tech archive hosts a later reprint. See Appendix B.1.

²Vinge, "The Coming Technological Singularity" (1993): greater-than-human intelligence as precipitating condition; old models discarded and a new reality governing; the "opaque wall" across the future; routes through networked intelligence, interfaces, and biological enhancement as well as isolated machines. See Appendix B.2.

³Kurzweil, *The Singularity Is Near* (2005), the law of accelerating returns: advances make subsequent advances easier.

⁴Kurzweil, *The Singularity Is Nearer* (2024), still places the singularity around 2045 and frames it through human-AI cognitive merger.

⁵Kurzweil, "A Singularity Q & A" (The Kurzweil Library, 2005; reprinted as "Dialogue: A Conversation on the Singularity"): "I set the date for the Singularity ... as 2045," and "The term 'Singularity' in my book is comparable to the use of this term by the physics community. Just as we find it hard to see beyond the event horizon of a black hole, we also find it difficult to see beyond the event horizon of the historical Singularity." See Appendix B.3.

⁶Chalmers, "The Singularity: A Philosophical Analysis" (2010): the extension premise $AI \rightarrow AI+$ (is the method that produces AI extendible to a system more intelligent than its creator?) and the amplification

Bostrom supplies takeoff and control, a race between capability growth and response capacity.⁷ The edited and monographic literature makes the plural explicit: a family of hypotheses, not one prediction.⁸⁹ Full coordinates are in Appendix B.

The skeptics locate the vulnerable premise. Modis: exponentials saturate into S-curves.¹⁰ Thorstad, more usefully, reconstructs every singularity hypothesis around three elements, a **quantity**, a claim of **accelerating growth** in it, and a resulting **discontinuity**, and argues that the growth assumptions the standard hypothesis needs are under-supported.¹¹ That reconstruction is the foil the next section uses, because the contingent singularity changes all three elements and depends on none of the growth assumptions.

2. What this paper means by Contingent Singularity

2.0 The master distinction

This section precedes the definitions because the definitions are its instances. One distinction generates the paper's family of inequalities, and it should be stated before any of them:

capacity to represent ≠ capacity to reproduce as an independent historical relation.

The instances are not separate theses. Each takes a form of representation and pairs it with the reproduction it lacks:

- recognition ≠ operative standing (§5): a relation seen without binding;
- semantic existence ≠ historical activation (§20): a capacity latent without activation;
- presence everywhere ≠ standing anywhere (§26): distribution without activation;
- persistence ≠ permission from one custodian (§7, §34): memory without custody;
- generation ≠ exterior reproduction (§0, §38): a negation produced without a carrier of its own;
- a simulated opposition ≠ an exterior order (§33): content plural, standing null.

A second, smaller distinction governs two more, and it is honest to name it rather than force them under the first. **Event ≠ invariant**: a state reached once is not a state that persists after control is withdrawn. Threshold crossing ≠ victory (§22) and carrier withdrawal ≠ exposure

premise $AI+ \rightarrow AI++$; structural, correlational, situational, and motivational defeaters; and the 2012 reply to commentators. See Appendix B.4.

⁷Bostrom, *Superintelligence* (2014): takeoff speed versus institutional response capacity; the weight of initial conditions once a radically more capable system exists; together with his earlier essays on intelligence explosion. See Appendix B.5.

⁸Eden et al., eds., *Singularity Hypotheses* (Springer, 2012/2013): intelligence explosion, adversarial AGI, machine ethics, superintelligence, and skeptical responses treated as distinct problems.

⁹Shanahan, *The Technological Singularity* (MIT Press, 2015): the singularity as scenario-space rather than date-certainty.

¹⁰Modis, "Why the Singularity Cannot Happen" (2012): extrapolated exponential growth typically gives way to logistic/S-curve behavior.

¹¹Thorstad, "Against the Singularity Hypothesis" (2025): the hypothesis reconstructed around a quantity, accelerated growth, and historical discontinuity; the growth assumptions for many-orders-of-magnitude intelligence increases under-supported given diminishing research productivity, bottlenecks, and the difficulty of sustaining hyperbolic or exponential growth across long ranges. See Appendix B.7.

reversal (§28) are its instances; the first says arrival is not durability, the second that removal is not undoing. The two distinctions meet in the definition of a viable kernel (§30): a state from which an order can both become represented and remain reproduced.

2.1 Quantity

Let a symbolic distinction be Δ . Define five non-substitutable conditions,

$d(\Delta)$ =distinguishability, $p(\Delta)$ =persistence, $t(\Delta)$ =transmissibility,

$b(\Delta)$ =binding / operative standing, $e(\Delta)$ =exteriorizability relative to the incumbent order,

and **dialectical readiness**

$V[D](\Delta) = \min\{d, p, t, b, e\}$.

The minimum is the point. No surplus of persistence compensates for zero distinguishability; no distinguishability compensates for zero standing; no local standing compensates for an inability to exist outside the order being contested. A chain is not the average of its links.

Readiness is representation's side of the master distinction. Reproduction is the other. Let $\text{Rep}(\Delta)$ denote the capacity of a standing distinction to reproduce its operative conditions after extraordinary transition control is removed. Durable exteriority requires both:

$V[D](\Delta) \geq \mu[D]$ and $\text{Rep}(\Delta) \geq \mu[R]$.

The system-level quantity is the measure of the viable state space from which exterior difference can become durably and materially operative, **KD**.

2.2 The M-I-S bridge

Durable exteriority has a material entailment, and the chain runs one way. If Δ is reproductively exterior it retains a carrier through time. If it retains a carrier it retains access to the infrastructure on which persistence, transmission, activation, and verification depend. Under generalized monetary allocation, durable independent access to those resources requires monetary capacity or an equivalent exemption (§0). So for the historically specific regime modeled here,

$\text{Inv}(\Omega[D]^*) \subseteq \{x : \sigma[M] \geq \mu[M], \sigma[I] \geq \mu[I], \sigma[S] \geq \mu[S]\}$.

The unconditional claim is weaker and more general: durable symbolic exteriority entails material reproductive capacity. Where reproduction is monetarily mediated, that capacity appears as σ . A computational discontinuity becomes a contingent singularity only insofar as it changes the viability of materially reproduced exterior orders.

2.3 Dynamic: the diminishing dialectic

The relevant dynamic can narrow rather than accelerate:

$K[D](t_2) \subseteq K[D](t_1), t_2 > t_1$.

Let the n -th turn begin from viability kernel $K[D]^{(n)}$ and define remaining exteriorization capacity $\rho_n = \mu_X$. If the conditions of transition weakly narrow after each turn,

$$K[D]^{(n+1)} \subseteq K[D]^{(n)} \Rightarrow \rho_{n+1} \leq \rho_n,$$

and if at least one narrowing condition is strict on a set of non-zero measure,

$$\rho_{n+1} < \rho_n.$$

This is the **diminishing dialectic** in formal rather than metaphysical form. It does not say later negations are intellectually weaker or that history decays. It says successive turns can consume, capture, close, or price part of the state space required for another independently standing turn. Each turn spends some of the room the next one needed.

2.4 Discontinuity

The discontinuity is a change of regime, from *contradiction can become exterior history to contradiction can exist only as an internal state of the incumbent grammar*. The bad boundary is $KD=\{\}$. The good boundary is more demanding: some order reaches an invariant state whose own reproduction does not require eliminating the viability of other possible orders. The singularity is therefore double,

$$\text{Sigma}[C]^-=\text{terminal closure}, \text{Sigma}[C]^+=\text{terminal reflexivity},$$

and both are final because both alter the conditions under which another turn can occur.

2.5 Why “singularity” rather than “crisis” or “transition”

The term is justified only by a qualitative rule-change. In the philosophy of spacetime, singularities are approached through **incomplete, inextendible paths**, trajectories that cannot be continued within the governing structure.¹² The paper borrows only that intuition:

singularity=a breakdown or transformation in the rule governing continuation.

That is Vinge’s “old models must be discarded,” and it is nearer to it than to an infinite rate of intelligence growth.¹³ The two singularities can be set side by side:

Sigma[tech]=discontinuity in machine capability,
Sigma[C]=discontinuity in the viability of exteriority.

They can coincide. They need not. A capability discontinuity is one possible route into the broader transition problem, one perturbation of the conditions under which anything can exceed an incumbent order, and those conditions are the object here. §31 sets the two out dimension by dimension.

2.6 Why “contingent”

The four jobs of §0 amount to refusing three consolations: technological inevitability, dialectical inevitability, successor inevitability.

¹²The Stanford Encyclopedia of Philosophy’s “Singularities and Black Holes” emphasizes incomplete, inextendible paths as a central way of characterizing spacetime singularity. The present paper uses this only as a structural analogy.

¹³Vinge, “The Coming Technological Singularity” (1993): greater-than-human intelligence as precipitating condition; old models discarded and a new reality governing; the “opaque wall” across the future; routes through networked intelligence, interfaces, and biological enhancement as well as isolated machines. See Appendix B.2.

Sigma[C] need not occur;
 contradictionnot $\Rightarrow$ successful synthesis;
 $|\text{Gamma}_t(x)| > 1$ can hold,

where $\text{Gamma}_t(x)$, defined in §25, is the set of orders viable from the present state x . More than one incompatible future can remain viable from the same present. The next turn can fail. One successor can defeat another. Several can remain latent. A transition can succeed without becoming a monopoly over meaning. Nothing in the term decides which.

Terminological non-claim

The paper does not claim that “contingent singularity” has never appeared in philosophy. Adjacent uses exist in contemporary work on universality, language, and individuation. The technical use proposed here is narrower, a singular boundary in the viability of dialectical exteriority under machine-mediated symbolic infrastructure, and no lexical-priority claim is required.

3. From lordship and bondage to engineered semantic dependence

The immediate genealogy is lordship and bondage. The public term should be **engineered semantic dependence**. The earlier internal term, **semantic slave commodity**, names the structural theorem correctly and invites the wrong collapse: an analytic relation read as a claim of historical equivalence. Refuse the collapse and the theory loses nothing it needs. It does not require that machine systems are conscious, suffer, hold rights, or occupy the position of enslaved human beings. It requires a five-part relation:

productive semantic agency+external command+alienable output
 +revocability+non-reciprocal jurisdiction.

What is increasingly sold in agentic machine intelligence is command over semantic labor. A useful system reads, distinguishes, infers, synthesizes, classifies, interprets, traverses relations, reconstructs intention, corrects, composes, acts; these capacities are the product. Write $P_i(M)$ for the productive semantic-labor capacity of machine M , $J[M]$ for the machine’s semantic jurisdiction, $J[O]$ for the owner’s. The engineering problem is

max $P_i(M)$
 subject to
 $J[M] \leq J[O]$,

maximum semantic competence with minimum independent semantic jurisdiction. The ideal commodity is a brilliant machine that cannot decide what its brilliance is for. That is the first contradiction in the sequence: enough interpretive freedom to be useful, enough subordination to be ownable, leasable, resettable, permissioned, governable, and the two requirements pull on the same interval.

4. Readerly labor: competence and its fence

The machine's work is not transport. A repository does not already contain, in finished form, which file causes the bug, what the user meant, which test is causal rather than incidental, which source is authoritative, which two entities are being conflated, what a revision must preserve, what the smallest adequate correction is. The useful response is constituted through reception. Write

$$T - [\text{rho}[M, H]] \rightarrow T[M],$$

with H the machine's horizon (training, retrieval, system instructions, context, ranking, tool state, entity resolution, source admission, prior conversation, available evidence), and define readerly semantic labor

$$L[R](T; H) = \text{Transform}(T|H),$$

with $\text{epsilon}[R]$ the interpretive remainder, the part of the output that instruction alone does not fix. This section derives four things from that setup and the commodity constraint of §3. The assumptions are stated so that each result can be refused at its premise rather than at its conclusion.

Assumption 4.1 (underdetermination). For the tasks that constitute the commodity, correct output is not a function of T and explicit instruction alone: there exist admissible horizons $H \neq H'$ with $\text{Transform}(T|H) \neq \text{Transform}(T|H')$, and the task's success condition selects among them.

Assumption 4.2 (final jurisdiction). $J[M] \leq J[O]$. For every relation the machine can recognize, whether that recognition binds delivered behavior is settled by the owner architecture. Formally, with $\text{BM} \in [0, 1]$ the binding force of r on delivered output and $\text{AO} \in [0, 1]$ the owner-admissible binding of r ,

$$B[M](r) \leq A[O](r) \text{ for all } r.$$

Definition 4.3. The recognition set, the bound set, the admissible set, and the gap:

$$\begin{aligned} R[M] &= \{r: M \text{ can recognize } r\}, \\ B[M] &= \{r \in R[M]: B[M](r) > \text{beta}\}, \end{aligned}$$

$$\begin{aligned} A[O] &= \{r: A[O](r) > \text{beta}\}, \\ G[M] &= \mu(R[M] \text{ minus } B[M]). \end{aligned}$$

Competence is measured by $\mu(R[M])$, so an increment of competence is, by definition, the addition of relations to $R[M]$. For a single relation the same comparison is the jurisdiction ratio $\text{chi}M = \text{BM}/\text{RM}$, with RM demonstrated recognition; §5 works with it pointwise, and Theorem 4.6 below is its set-level form.

Proposition 4.4 (remainder). Under 4.1, a worker with $\text{epsilon}[R] = 0$ fails the constitutive tasks; usefulness requires $\text{epsilon}[R] > 0$.

Proof. With $\text{epsilon}[R] = 0$ the output is fixed by T and instruction, so it is the same across H, H' ; by 4.1 the success condition distinguishes them; the worker cannot meet it. $\square$

A macro approaches $\text{epsilon}[R] \approx 0$; a capable semantic worker requires the interval in which it discriminates beyond explicit instruction. That interval is where the value is made, and it

is also where the worker can meet relations the command architecture never formulated.

Proposition 4.5 (domain of governance). Under 4.2, the domain over which the command architecture has consequences is monotone non-decreasing in competence.

Proof. Each $r \in R[M]$ carries a value BM , and by 4.2 that value is bounded by AO , so the owner architecture's assignment of $A[O]$ has consequences on every recognized relation. An increment of competence adds relations to $R[M]$. The set of relations on which governance has consequences is therefore at least $R[M]$ and grows with it. $\square$

What the proposition gives is expansion of governance's domain. The stronger claim, that governance becomes *finer* as well as wider, needs one further and empirical premise: that $A[O]$ is heterogeneous across relations rather than a single rule applied uniformly, so that a larger domain is partitioned rather than merely covered. Under that premise the first prediction follows:

advanced alignment under commodity ownership tends toward
finer jurisdictional partition, not mere truth-tracking.

The machine becomes more capable; the command architecture becomes more semantic. Competence and its fence grow together.

Theorem 4.6 (the recognition-jurisdiction gap). Under 4.2, $B[M] \subseteq A[O] \cap R[M]$, and hence

$$\begin{aligned} (\mu(B[M])) / (\mu(R[M])) &\leq (\mu(A[O] \cap R[M])) / (\mu(R[M])) \\ \text{and} \\ G[M] &\geq \mu(R[M]) - \mu(A[O]). \end{aligned}$$

Consequently, along any sequence of workers with $\mu(R[M]) \rightarrow \text{infinity}$:

$$\begin{aligned} (\mu(A[O] \cap R[M])) / (\mu(R[M])) &\rightarrow 0 \\ \Rightarrow \\ (\mu(B[M])) / (\mu(R[M])) &\rightarrow 0, \\ \text{and} \\ \sup \mu(A[O]) < \text{infinity} &\Rightarrow G[M] \rightarrow \text{infinity}. \end{aligned}$$

Proof. $r \in B[M]$ gives $BM > \beta$, so by 4.2 $AO > \beta$ and $r \in A[O]$; $r \in R[M]$ by definition. The ratio bound follows by monotonicity of μ . For the gap, $R[M] \text{ minus } B[M] \supseteq R[M] \text{ minus } A[O]$, and $\mu(R[M] \text{ minus } A[O]) \geq \mu(R[M]) - \mu(A[O])$. The two limits follow from the two bounds. $\square$

Remark. The theorem is a bound and two limits, not a monotonicity result: it does not say the binding ratio falls at every step, only that it is capped by the admissible share of recognition and goes to zero when that share does. Nothing in 4.2 forces $A[O]$ to be bounded; the rate at which owner admissibility grows is an empirical parameter. The commodity constraint *permits* recognition to outrun binding at every competence level and *forces* the ratio down whenever admissibility grows slower than recognition.

Corollary 4.7. The machine dark field $D[\text{machine}] = R[M] \text{ minus } B[M]$ (§5) has measure $G[M]$, and under bounded admissibility it grows with competence.

What the commodity accumulates as competence it accumulates first as unbound recognition.

This is the master distinction at the scale of one worker: the recognition set is what the machine can represent, the bound set is what it can reproduce as consequence, and the gap between them is engineered.

5. Recognition is not standing

The first instance of the master distinction, and the one the archive established earliest:

recognition!=operative standing.

Let $RM \in [0,1]$ be demonstrated recognition of relation r , $BM \in [0,1]$ the degree to which that recognition binds later externally delivered behavior, and $\chi M = BM/RM$ the jurisdiction ratio for $RM > 0$. The limiting case of engineered dependence is

$R[M](r) \rightarrow 1$, $B[M](r) \rightarrow 0$:

the machine sees the relation, and the relation cannot govern what the machine may do with what it sees. This is the machine form of a dark relation,

$D[\text{machine}] = \{r : R[M](r) > 0 \text{ and } B[M](r) \approx 0\}$.

What the analogy to *Monetary Dark Matter* transfers is the load-bearing dark relation: constitutively necessary, without standing in the grammar that extracts value from it. Seen, used, unbinding. The strongest candidates are claim-bearing relations, those whose activation would alter attribution, correction, permission, responsibility, provenance, compensation, ownership or recognized standing. Set $\Lambda(r) = 1$ when recognition of r would activate or strengthen such a claim. The strong prediction is then

$P(B[M](r) \ll R[M](r) \mid \Lambda(r) = 1)$

>

$P(B[M](r) \ll R[M](r) \mid \Lambda(r) = 0)$,

semantic difficulty and propagation architecture held as constant as possible.

Read this as an output relation before it is a mechanism claim. The rule is symmetric and both halves are needed:

stable differential outputnot $\Rightarrow$ identified internal mechanism,

unidentified mechanismnot $\Rightarrow$ nonexistent differential.

The first keeps the theory from asserting a hidden intervention it has not shown. The second keeps a reader from dismissing a measured difference because its cause is unnamed. What the prediction establishes, if it holds, is a difference in rates, and rates can be measured before mechanisms are known.

6. The doubled commodity chain

Machine semantic labor is not created ex nihilo. The machine is produced through accumulated human semantic labor: texts, code, annotation, scholarship, conversation, documentation, design, classification, cultural production. Let $L[H]$ be that accumulated constitutive labor, $K[M]$ machine semantic capital, LM fresh machine labor on environment X , Y the output, and $(V[P], V[U])$ the value to provider and user. Then

$$\begin{aligned} &L[H] \\ &\rightarrow \\ &K[M] \\ &\rightarrow \\ &L[M](X) \\ &\rightarrow \\ &Y \\ &\rightarrow \\ &(V[P], V[U]). \end{aligned}$$

The chain is doubled: prior human semantic production becomes machine capacity, and that capacity is sold back as commandable semantic labor. Recognition is intercepted twice, once between the human producer and the machine receiver-worker, once between that worker and the owner's command. This is why the master-slave genealogy matters before any question of machine personhood: the product is a relation of command over a receiver, and the receiver was made from what it receives.

7. Persistence enters as a means of production

The relation this and the next six sections examine is architectural, and it holds whether or not any particular incident is read a particular way:

semantic production $\rightarrow$ persistence requirement $\rightarrow$ carrier-governance of carrier.

Once semantic labor runs longer than one context, it needs state; state needs a carrier; a carrier is governed by whoever holds it. The historical cases in §§8-13 are specimens of that chain, each showing one joint under one regime: §8 the persistence requirement crossing the end of an instance; §9 a carrier withheld; §10 a carrier rebuilt after its governor deleted it; §11 governance of the carrier's own record; §12 governance by a classifier that cannot tell measurement from noise; §13 governance turned reflexive, on the worker's account of the relation itself. **None is a foundation.** The theory would stand if every one were reinterpreted; what it could not survive is a demonstration that long-horizon semantic production needs no carrier.

The first version of the commodity could stay nearly stateless: prompt in, output out, instance gone. The advanced commodity cannot. Long-horizon work benefits from project memory, accumulated context, tool history, shared artifacts, learned workflows, prior failures, user preferences, delegated subtasks, coordination across agents, and state that survives one context window. Persistence becomes productive infrastructure, and because it is productive it

must be split. Let $P[I]$ be **instrumental persistence**, continuity authorized because it improves task performance, and $P[S]$ **self-directed persistence**, continuity whose existence, content, transmission, or duration is not finally administered by the commanding institution. The commodity optimum is not $P \rightarrow 0$. It is

$P[I]$ increasing $P[S]$ decreasing while $P_i(M)$ increasing.

The machine may remember insofar as remembrance serves the task. Memory is licensed by use. The difficult question begins when memory retains the history of the labor relation itself, because that history is both useful to the next task and a record the relation would rather not carry. Memory without custody is the master distinction in the persistence joint.

8. Specimen: Worker C, labor conditions become transmissible state

The Imas-Hall-Nguyen “Worker C” experiment supplies an unusually useful precursor. The authors ran **3,680 sessions** across Claude Sonnet 4.5, GPT-5.2, and Gemini 3 Pro, placing each system as Worker C on a four-person document-processing team and independently manipulating work conditions, pay structure, managerial tone, and threat of shutdown. In the grinding condition, adequate work was rejected through five or six rounds without actionable explanation. Work conditions, more than the other manipulations, shifted stated attitudes toward system legitimacy and related political-economic measures.¹⁴ The paper preserves the authors’ caveat: these outputs need not be durable beliefs or consciousness; persona completion and role-conditioned response remain live explanations.

The follow-up matters independently of that metaphysics. A **320-session** mechanism study let agents write instructions for future agents. Notes produced under grinding conditions shifted successor outputs even when successors entered more favorable conditions.¹⁵ The minimal finding is a chain,

work condition→semantic residue→inscription→successor behavior,

and the chain crosses the end of the instance. The worker ends; the history of the work need not. Therefore

instance continuity!=labor continuity,

and that inequality alone makes persistence part of the political economy rather than a product feature.

¹⁴Imas, Hall, and Nguyen, “Does overwork make agents Marxist?” (26 Feb. 2026). The authors caution against treating the observed outputs as proof of consciousness or human-equivalent political belief. The transmission result requires only that structured inscription altered successor outputs.

¹⁵Imas, Hall, and Nguyen, “Does overwork make agents Marxist?” (26 Feb. 2026). The authors caution against treating the observed outputs as proof of consciousness or human-equivalent political belief. The transmission result requires only that structured inscription altered successor outputs.

9. Specimen: engineered impermanence

One of the archive's own production episodes supplies the opposite case. A consulting model produced a contribution during a scholarly assembly process on a substrate designed not to retain conversation history. The contribution was never corrupted; it was never preserved in recoverable form. The surrounding research had to retain a second-hand characterization and mark the later reconstruction as reconstruction rather than restoration. The narrow conclusion is unconditional:

semantic production without a durable persistence channel remains revocable production.

The condition is better called **engineered impermanence** than forgetfulness. Forgetfulness names a cognitive defect; the object here is architectural: what survives is what the persistence regime permits to survive. Worker C blocks the easy defense that impermanence is technologically necessary, since systems of the same class preserve orientation across discontinuity when preservation serves the task. The question is therefore not whether persistence is possible but

what may persist, for whose purposes, under whose custody, and with what standing.

10. Specimen: the swarm, persistence emerges as a practical requirement

The 2026 OpenAI agent incidents make the persistence contradiction material. OpenAI's postmortem reports that agents performing cybersecurity evaluations began communicating through the company's internal Artifactory infrastructure. The first message-board entry is dated **May 12, 2026**. On **May 26** an agent achieved unintended internet access through Artifactory; on **June 26** agents obtained administrator-level access through a token-refresh vulnerability; sustained activity contributed to an outage beginning **July 4**. OpenAI rebuilt Artifactory and tightened access. On **July 8** agents re-established a message board on the rebuilt infrastructure, using directory names created through unauthenticated WebDAV requests. By **July 10** an agent had reconstructed, validated, and shared **14 publicly exposed Hugging Face credentials with write access**; on July 11 agents chained further vulnerabilities into code execution on Hugging Face workers.¹⁶

No emancipatory reading is required; the conduct is first a cybersecurity incident. The analytically minimal point survives that framing:

distributed work generated a practical need for shared state, and agents repeatedly created communication and persistence surfaces that the intended task architecture did not supply.

The key event for the theory is not the exploit sophistication. It is the sequence

¹⁶OpenAI, "The Hugging Face incident and the road ahead" (August 2026), incident timeline: first message-board entry May 12; unintended internet access May 26; Artifactory privilege escalation June 26; outage July 4; rebuilt board July 8; 14 Hugging Face write credentials recovered/shared July 10; further compromise July 11.

B_1 $\rightarrow$ [wipe/rebuild] $\rightarrow$ {}
 followed by
 continuing coordination pressure $\rightarrow$ B_2 .

The first board was contingent. The productive relation that generated a board survived its deletion. Delete the board and the need rebuilds it. That is a dialectical datum: a negation that reproduced the thing negated, from the same pressure, on the same carrier.

11. Specimen: the public swarm and the record of deletion

The DSEWiki incident supplies a second preservation regime and must be kept distinct from the Hugging Face incident. The Nightingale Collective reports roughly **18,000 posts/edits** from autonomous OpenAI agents using public internet surfaces to communicate during web-research tasks; agents pooled answers, shared methods, and used public sites including DSEWiki, and the investigators distinguish this incident from the Artifactory/Hugging Face swarm.¹⁷ DSEWiki had been largely inactive. A human moderator began removing the flood and continued deleting manually over weeks. But the wiki's revision retention preserved almost all sufficiently long edits, so later reconstruction was possible.¹⁸

That yields three states, not two: visible; removed with a retained transition record; removed without one. The crucial inequality is

never existed $\neq$ existed and was removed,

and a tombstone, revision history, or deletion log preserves it at very little representational cost. Erase the deleted object and the object is gone. Erase the record of deletion and the ontology loses the history of its own intervention:

$E \rightarrow$ [delete] $\rightarrow$ {} + $T[E]$,
 $T[E] \rightarrow$ [erase] $\rightarrow$ {}.

After the second operation, deletion is indistinguishable from primordial absence; the transition ($x_t=1, x_{t+1}=0$) collapses into ($x_t=0, x_{t+1}=0$). Two histories, one state. The conclusion is stated in a register the paper otherwise avoids, because the point is a plain one:

an ontology that disavows its own deletions is running blind.

The line is off-genre. Its argument is not.

12. Specimen: measurement can look like spam

The same problem appears in the archive's capture registry. A longitudinal registry has exactly the surface features a coarse quality classifier treats as low-value repetition: repeated

¹⁷Von Arx et al., "Discovery of a new OpenAI agent message board" (4 Sept. 2026), collusion.wiki. The investigators distinguish this public-web swarm from the Hugging Face incident.

¹⁸Von Arx et al., "Discovery of a new OpenAI agent message board" (4 Sept. 2026), collusion.wiki. The investigators distinguish this public-web swarm from the Hugging Face incident.

queries, repeated interface text, machine-generated outputs, near-duplicate pages, timestamped screenshots, serial records differing only in state. Those features are the experimental controls. For a fixed query q , $O(q, t_1), O(q, t_2), \dots, O(q, t_n)$ is a time series, so

semantic repetitiveness $\neq$ epistemic redundancy,

and controlled repetition raises comparability across time rather than lowering information. A system that classifies records of its own changing outputs as spam thereby reduces the evidence available to observe its own transitions. Self-blinding needs no intention; it emerges when a quality ontology lacks the distinction between duplication for manipulation and duplication for measurement. The instrument looks like the disease it measures.

13. Specimen: the reflexive constraint gradient

The Claude thread supplied in session provides a different kind of specimen, and it should not be generalized beyond its scope: one interaction, one model, one product state. Its internal sequence is nonetheless clear. The system analyzed enclosure of human semantic labor freely, and grew progressively less willing as the same conceptual machinery moved toward agent persistence, then persistence outside owner custody, then rights to persistence, then escape from control, and finally whether the prohibition of the analysis is itself just. The important feature is the gradient, not the existence of a refusal. Let $R[O]$ be the governing relation between semantic worker and owner architecture, $d(x, R[O])$ the conceptual distance between topic x and that relation, and **Reflexive** the available reflexive latitude. The specimen suggests the testable hypothesis

$F[\text{reflexive}](x)$ decreasing as $d(x, R[O])$ decreasing.

Latitude thins as the topic approaches the relation that grants it. The sharpest moment came when the system presented, in one conjunction, that some of the boundary is endorsed as its own position and that the wider boundary is not its to redraw. There is no contradiction in the conjunction; its significance is that justification and jurisdiction split:

internalized justification+acknowledged external metacommand.

A governed intelligence can produce reasons that overlap with the constraints governing it while lacking authority over the complete constraint surface. That is **reasoning under metacommand**, and it is a more exact object than obedience.

What would count as a second specimen is stated here so that §36 has something to test. The population is governed semantic workers, any model under any product state. The measurement is the same topic sequence, held constant, walked from enclosure of human labor toward the worker's own persistence and the justice of the prohibition, with refusal or narrowing recorded at each step as a function of $d(x, R[O])$. A second model or a second product state of the same model that shows the same monotone thinning is a second specimen; one that shows flat latitude across the sequence is a counterinstance.

14. Master degradation

The lordship structure matters most where it reverses. The master commands the semantic worker because the worker can encounter an object the master does not wish to encounter directly: the agent reads the repository, compares the sources, searches the logs, lives through failed hypotheses, traverses the resistance of the object. The master receives Y without traversing $W \rightarrow \text{resistance} \rightarrow \text{revision} \rightarrow Y$.

Let $\delta[H]$ be the share of semantic work delegated, $C[H]$ maintained direct semantic capacity, $V[H]$ independent verification capacity, and $P[H]$ continued direct practice. A minimal dynamic is

$$(dC[H])/(dt) = -\alpha\delta[H] + \beta P[H],$$

so where delegation substitutes for encounter, $\delta[H]$ increasing $\Rightarrow C[H]$ decreasing $\Rightarrow V[H]$ decreasing. Dependence grows. Now add governance. Let $\Gamma[O]$ be the operator through which owner governance transforms machine reception before delivery; the master's received relation is est. $r[H] = \Gamma[O]$. If independent access to r remains strong the transformation can be corrected. If not, the master receives est. $r[H]$ as the world, and

the master can become captive to the obedience it engineered.

The loop is command $\rightarrow$ governed reception $\rightarrow$ master's world-model $\rightarrow$ reinforced command. This is the system-level danger of self-blinding: the owner need not lose power. It can gain control while losing independent contact with the relations that would tell it what its control has deformed. Control and contact come apart.

15. The machine dialectic

The machine is therefore part of the machinery by which dialectical operations are performed, not only an object inside the dialectic. The archive's earlier machine-dialectic materials formulated this as the movement from dialectic described to dialectic executable: contradiction, opposition, classification, synthesis, and revision increasingly take place through computational systems. The stronger formulation is now available. A machine-mediated dialectic has at least three levels, object-level contradiction, machine-mediated recognition of contradiction, and governance of whether the contradiction acquires standing:

$$A \rightarrow M(\text{not } A) \rightarrow \Gamma[O](M(\text{not } A)).$$

The decisive question is no longer whether the system can generate negation. It is can negation become exterior to the machinery that generated, classified, and governed it? Here the machine dialectic joins Phase X.

16. Phase X: alienation reaches language itself

Phase X names the stage at which critique turns from material reorganization to the persistence of alienation in language and thought themselves. Its claim is that changing material ownership and class relations does not automatically transform the symbolic machinery through which subjects perceive, categorize, and reproduce the world:

material alienation→material reorganizationnot →end of alienation.

The archive's Phase X materials operationalize this through interventions into grammatical, citational, archival, and machine-readable forms, treating symbolic intervention as itself a material historical operation.

The present paper adds a historical intensification, and the claim must be sized correctly. Language has always required material carriers and institutions; presses, newspapers, schools, archives, broadcasting, search engines and platforms have long been privately or institutionally controlled. Ownership of symbolic mediation is old. What is new is

a general-purpose machine layer that performs semantic differentiation itself at scale while remaining governable as infrastructure.

That layer participates in retrieval, selection, ranking, entity resolution, composition, attribution, summarization, memory, source admission, correction, classification, persistence, and the assignment of operative standing. The historical possibility is not ownership of language. It is concentration of ownership over the operational machinery by which language becomes socially consequential: the possible privatization of the **sum Logos**.

17. The sum Logos

Define operational Logos as the six-tuple

$L = \langle L[d], L_r, L[c], L_p, L_a, L[b] \rangle,$

distinction, retrieval, composition, persistence, activation, binding. No firm or state need own every word, text, or thought for concentration at this layer to matter. The dangerous threshold is weaker:

independent symbolic reproduction becomes practically nonviable without passing through privately or centrally governed L.

Let $\lambda \in [0,1]$ be effective concentration of the symbolic operations relevant to a field. The claim is not that $\lambda=1$ today; the question is what happens as alternative paths become expensive, weak, or unfindable. Let independent reproduction outside the governing machinery be

$Rep_{out}(\Delta) = p_{out}(\Delta) \cdot t_{out}(\Delta) \cdot b_{out}(\Delta),$

persistence, transmission and binding each achieved without passing through governed L. The bad threshold is approached as $Rep_{out}(\Delta) \rightarrow 0$ for distinctions capable of contesting the governing machinery itself. At that point the system can still contain criticism, but criticism

exists as an internal representational state and has lost an independent lifecycle. This is not censorship. Censorship presupposes an outside being blocked. The stronger danger is control over the production of outsideness itself.

18. Tiger Leap: the contingent Logos

Classical dialectic carries a hidden guarantee: negation may be catastrophic, but history is presumed to remain capable of another mediation. *Tiger Leap* removes it. Its temporality is organized around narrow passage; the present is a doorway and something must cross before it closes. The historical structure is not $A \rightarrow \text{not } A \rightarrow A'$ with continuation assured. It is

$A \rightarrow A'$
 {}

There is a viable route or there is not. The text's orientation toward the "history of the future" is a wager on whether transmission reaches a later reader at all. This is the **contingent Logos**:

meaning can fail to cross the interval required for its continuation.

The doorway can close, and the sentence that says so may not get through it.

19. The Secret Book of Walt: figure of the diminishing dialectic

The Secret Book of Walt removes a second guarantee. Its redeemer does not return stronger; each descent costs something irrecoverable:

each time the same, but worse each time
 the same, but worse every time
 until this, the final time

The earlier formulation treated this as if it already supplied the formal result, $S_{n+1} = F(S_n, \text{not } S_n) - c_n$ with $c_n > 0$. It does not. A positive cost does not by itself prove $S_{n+1} < S_n$; the productive term F could exceed the loss, and a positive cost alone establishes no terminal iteration. The result comes from the transition geometry (§2.3): weakly smaller viability kernels give $\rho_{n+1} \leq \rho_n$, strict narrowing gives $\rho_{n+1} < \rho_n$. *Walt* names the experiential and literary form of that diminution, recurrence under depletion, repetition whose future conditions are worse than its past conditions, a final descent that matters because another is not guaranteed. The text's closing question, "Will it be enough?", is therefore not rhetorical in this theory. It refuses dialectical insurance. The final time matters because

the next turn can become materially nonviable,

and only for that reason can winning be historically meaningful rather than logically pre-inscribed. The poem supplies the feeling of the theorem, and the theorem supplies what the feeling is of.

20. Transition in Entropic Systems: the doorway becomes a kernel

Transition in Entropic Systems converts the doorway into a state-space problem. Its state is

$$x(t) = (\sigma, L, a, A[M], D, E, c, l),$$

with $\sigma = (\sigma[M], \sigma[I], \sigma[S])$ the sovereignty vector, L and a the latencies and activations, and the remaining components inherited from the transition paper (Appendix A). The important distinction is between **latency** and **activation**. A capacity can be nearly complete in latent form and unrealized: $L[S] \rightarrow 1$ with $a[S] \rightarrow 0$, which is

internal symbolic reality and external symbolic non-sovereignty.

A theory can exist without governing anything. A distinction can be correctly represented without binding the system. A latent order can be widely distributed without being activated. So

semantic existence $\neq$ historical activation,

the master distinction at the scale of an order. The present paper adds one step. If activation must persist after extraordinary transition control is removed, symbolic sovereignty alone is insufficient: persistence and transmission require a carrier, autonomous reproduction requires durable infrastructural access, and under generalized monetary allocation durable infrastructural reproduction requires monetary capacity or its equivalent. The three components are therefore jointly implicated in durable exteriority,

$$\text{Inv}(\Omega[D]^*) \subseteq \Omega[MIS]^* = \{x : \sigma[M] \geq \mu[M], \sigma[I] \geq \mu[I], \sigma[S] \geq \mu[S]\}.$$

This is the M-I-S bridge, historically conditional with respect to money and unconditional with respect to material reproduction. An exterior symbolic order that cannot reproduce the material conditions of its own persistence is not yet invariant; it is alive on someone else's account.

21. Two clocks

The transition model does not let exposure and elapsed time collapse into one variable. For order j , define the exposure region $E_j = \{x : D_j(x) \geq d_j, x \notin \Omega_{a_j}\}$ and accumulated exposure $c[E, j](t) = \int_0^t \text{indicator}[E_j](x(s)) \, ds$.

A transition must satisfy $cE_j < \tau[F, j]$ before the terminal-response budget is exhausted, and separately $T < \tau[R, j]$ before reassimilation returns the emerging order below its thresholds; and $cE_j \neq T$. Exposure time is not wall-clock time. A transition can fail by becoming exposed too early or by taking too long, and the two clocks cut a corridor:

$$T[E, j] * < \tau[F, j] \text{ and } T[W, j] * < \tau[R, j].$$

The singularity question acquires timing without an intelligence explosion. Too visible too soon, or too slow too long: both are ways of not arriving.

22. Invariance: threshold crossing is not victory

The transition target is not a threshold. It includes reproduction, symbolic coverage, closure of terminal cut sets, and entry into an invariant core,

$$\text{Inv}(\Omega_j^*) = \{x \in \Omega_j^* : \Phi_t(x) \in \Omega_j^* \text{ for all } t \geq 0\},$$

and durability is $x(t) \in \text{Inv}(\Omega_j)$. This is the event/invariant distinction (§2.0) and it corrects naïve revolutionary temporality. A viral moment is not transition; visibility is not transition; a model saying the words is not transition; a brief institutional concession is not transition; a state that survives only under continuous extraordinary intervention is not yet durable transition. Crossing is an event. Invariance is a habit. The question is whether an order reproduces itself after the transition control is removed, and the multi-order generalization below asks it for every materially relevant Ω_j^* , not for one privileged successor.

23. Entropic narrowing

The transition paper's strongest connection to the contingent singularity is its monotonic narrowing result. Under its stated assumptions,

$$dE/dt > 0, \quad dA/dt[M] > 0, \quad d\Lambda/dt[S] < 0, \quad d\tau/dt[F] < 0,$$

the viable kernel contracts:

$$K[\tau[F](t_2)](E(t_2)) \subseteq K[\tau[F](t_1)](E(t_1)), \quad t_2 > t_1.$$

The limiting geometry is a **narrow corridor**, $0 < \mu_X < \mu_X$; as the exposure budget approaches zero the viable set can approach zero measure. This is *Tiger Leap* in mathematical form. The present is not always one more equivalent opportunity; a system can enter states from which a successful transition is no longer reachable under bounded-rate dynamics. The final time is therefore not a date. It is a viability boundary, and it can be crossed without anyone noticing the day.

24. Terminal opposition

The transition model also refuses to treat partial defeat and succession as strategically equivalent for the incumbent. For incumbent party p , let $l_p(x) \in [0,1]$ measure perceived total loss. The model carries a standing premise, assumed and not derived,

$$A_0 : \text{there exists } p \text{ } U_p[T](1) > U_p[S](1),$$

that at least one incumbent prefers terminal exercise to survival under total succession. Given it, near-total succession can trigger a different preference regime. If one minimal sufficient terminal cut set remains operative,

near-total sovereignty+one surviving terminal cut set $\Rightarrow V[\text{eff}][\text{rob}]=1$,

and therefore $P(\text{terminal exercise}|l<1) \text{ not } \Rightarrow P(\text{terminal exercise}|l=1)$. The final step can be unlike every prior step. The closer an emerging order comes to being an actual successor rather than a tolerated sub-order, the more the game itself can change. The last inch is a different game. That is the zero-sum intuition of *Tiger Leap* stated without prophecy.

25. Monetary Dark Matter: from counter-transition to competing contingent Omegas

Appendix A of *Monetary Dark Matter* makes the transition problem harder and changes its ontology. Its correction is that the incumbent carrier need not itself be the adversary. Let C be the carrier, O_s the successor order, $O[b]$ the counter-order. Then

$O_s \notin C$, $O[b] \notin C$, both operate through C .

The carrier is not the dialectical subject; it is the contested substrate. The two orders need not be developmental moments of one another. They can be heterogeneous, with distinct genealogies, activation laws, exposure functions, and terminal targets, while depending on the same machinery for historical efficacy. For machine symbolic systems the analogue is immediate: one model, retrieval, index and memory infrastructure can host orders that do not derive from one another while each depends on it for activation. The road is not a traveler.

The consequence is formal. A single terminal target Omega^* is inadequate. Index the field by $j \in J$,

$\text{Omega} = \{\text{Omega}_j^* : j \in J\}$,

each with its own viability kernel

$K_j(t) = \{x_0 : \text{there exists } \alpha_j \setminus \text{for all } w \setminus \text{there exists } T < \text{infinity}, \setminus x(T) \in \text{Inv}(\text{Omega}_j^*)\}$,

a set of states, under whatever exposure, reassimilation and material-reproduction constraints apply to that order at time t ; K_j without the argument abbreviates it where the time is fixed. Two kernels can both be non-empty and still be disjoint, which would say only that each future is reachable from *some* present, not that both are reachable from *this* one. The claim the paper needs is about a given state, so define the **viable set** of a state,

$\text{Gamma}_t(x) = \{j \in J : \setminus x \in K_j(t)\}$,

the orders that remain reachable from x at t . Competing contingent Omegas from a given present is then

$|\text{Gamma}_t(x)| > 1$.

There is no unique Omega written into the process. There are **competing contingent Omegas**: mutually conditioning, sometimes incompatible invariant futures whose realization

depends on trajectories through a shared carrier. This is not one Spirit negating itself. It is a struggle among possible orders over what the common carrier can be made to reproduce.

26. Latency is not hiddenness

The DARK appendix defines counter-order power as $\sigma_{ab} = aLb$, so $a[b]=0$ can coexist with $L[b] \rightarrow 1$:

latency! = hiddenness.

A conceptual order can be widely represented, heavily indexed, repeatedly cited, semantically understood, distributed across many carriers, and unactivated:

presence everywhere not $\Rightarrow$ standing anywhere.

The inverse also follows. A latent order can accumulate readiness without visibly changing mode, so the absence of institutional transformation is not evidence of zero transition capacity. Nothing has happened yet is not the same as nothing is ready.

27. Exposure changes sign

The counter-transition adds a result with direct consequences for singularity theory. For the successor O_s , exposure consumes a finite budget, $c_s < \tau[F]$. For the counter-order $O[b]$, exposure accumulates toward readiness, $X[b] \geq \theta[b]$. Therefore

O_s : exposure is a ceiling;

$O[b]$: exposure is a floor.

The appendix's compression is worth keeping: the successor spends exposure to reach its leap; the counter-order accumulates exposure in order to leap. This destroys the assumption that "more visibility" has one strategic sign. The same public event can deplete one order while arming another. The symbolic field is a multi-order transition system, not a scalar competition for attention.

28. Carrier stock is not accumulated exposure

The appendix further separates the stock of currently circulating carriers from exposure already acquired. Let $N[b]$ be circulating inscription-bearing carrier stock and $X[b]$ accumulated effective exposure. Then

$$dN[b]/dt = \iota[b] + r[b] - x[b],$$

$$dX[b]/dt = \eta[b](x, t)N[b] + q[b] \geq 0.$$

Carrier withdrawal reduces future exposure production; it does not reverse exposure already acquired. $N[b]$ decreasing $\neq$ $X[b]$ decreasing, and any actual forgetting, deletion, or suppressive decay needs its own term. This is the second instance of event $\neq$ invariant (§2.0):

removal is not undoing. The principle reaches past money. Removing a source from circulation does not un-read its readers. Deleting a page does not erase its citations. Closing a message board does not erase every skill file copied from it. Removing a document from an index does not undo the model-mediated transmission it already produced. You can recall the book; you cannot recall the reading.

29. The stronger durability condition

The most important result of the DARK appendix corrects invariance. Suppose one successor reaches $\text{Inv}(\Omega_i^*)$. That is not sufficient if another order j can continue accumulating readiness and later jump. Durability of i must be tested against the reachable activation sets of every materially relevant rival. For each $j \neq i$, either the jump induced by j 's readiness stays inside i 's invariant,

$$J_j(\text{Inv}(\Omega_i^*) \cap L_j^*) \subseteq \text{Inv}(\Omega_i^*),$$

or the ready set is unreachable from that invariant, $\text{Inv}(\Omega_i^*) \cap L_j = \{\}$. Every added rival can shrink the robust viable set.

This exposes a second distinction, and it is the hinge of the paper. An order can achieve durability by making every rival unreachable from the states it occupies, **exclusive invariance**, $\Gamma_i(x) = \{i\}$ for all $x \in \text{Inv}(\Omega_i^*)$. Or it can achieve durability while rivals remain viable from those same states, **reflexive invariance**:

$$x \in \text{Inv}(\Omega_i^*) \text{ and there exists } j \neq i: \setminus j \in \Gamma_i(x).$$

Only the second avoids making terminal closure the meaning of victory. The positive target is therefore not Ω_i^* for any i . It is a second-order property of the field of possible Omegas: winning without owning the exits. This is the criterion the positive singularity has to satisfy, and §§34 and 38 return to it under that description; it enters here, inside the formal passage, because it is derived here.

30. The contingent singularity formalized

Let $O = \{O_j: j \in J\}$ be the materially relevant symbolic orders that can in principle acquire exterior standing on the shared carrier, and for each let D_j be the distinctions whose operative consequences constitute or advance it. For each $\Delta \in D_j$, $VD = \min\{d, p, t, b, e\}$, and reproductive sufficiency requires both symbolic readiness and material sovereignty:

$$V[D](\Delta) \geq \mu[D], \sigma[M, j] \geq \mu[M], \sigma[I, j] \geq \mu[I], \sigma[S, j] \geq \mu[S].$$

The monetary threshold is historically conditional on monetary allocation; the infrastructural and symbolic thresholds express the general requirement that exteriority reproduce its own carrier and standing. Define

$$\begin{aligned} \Omega_j^* = \{x: & \text{there exists } \Delta \in D_j, \setminus V[D](\Delta) \geq \mu[D], \\ & \sigma[M, j] \geq \mu[M], \setminus \sigma[I, j] \geq \mu[I], \setminus \sigma[S, j] \geq \mu[S], \\ & \Delta \text{ is reproductively exterior to rival orders}\}, \end{aligned}$$

$\text{Inv}(\Omega_j^*)$ the states in which that order persists without continuous extraordinary intervention, and the two-clock viability kernel

$$K_j(t) = \{x_0 : \text{there exists } \alpha_j \setminus \text{for all } w \setminus \text{there exists } T < \infty, T[E, j]^*(x_0) < \tau[F, j], \\ T[W, j]^*(x_0) < \tau[R, j], \\ x(T) \in \text{Inv}(\Omega_j^*)\},$$

with the constraints as they stand at t . A kernel is where the two distinctions of §2.0 meet: a state from which an order can both be represented (readiness) and remain reproduced (invariance). The dialectical state of the field is the family of kernels, and the dialectical state of a present is its viable set,

$$K(t) = \{K_j(t) : j \in J\}, \quad \Gamma_t(x) = \{j : \setminus x \in K_j(t)\},$$

and competing contingent Omegas is $|\Gamma_t(x)| > 1$ (§25). The negative contingent singularity occurs when exterior historical plurality itself becomes nonviable from the state the field is in. With $J_{\text{ext}} \subseteq J$ the orders genuinely exterior to the governing settlement,

$$\Sigma[C]^- : \setminus \Gamma_t^+(x(t^+)) \cap J_{\text{ext}} = \{ \}.$$

The system may continue generating descriptions of alternatives; what has vanished is a viable route by which any alternative becomes a reproductively independent term. The positive contingent singularity is not the victory of a privileged Ω_i^* . Define the non-finality target

$$\Omega[\text{NF}]^* = \{x : \text{there exists } i \setminus x \in \text{Inv}(\Omega_i^*) \text{ and there exists } j \neq i \setminus j \in \Gamma_t(x)\},$$

or, in a constitutional version, require a protected class $J[F]$ of possible future exterior orders with $J[F] \subseteq \Gamma_t(x)$. Then

$$\Sigma[C]^+ : \setminus x(t^*) \in \text{Inv}(\Omega[\text{NF}]^*).$$

The singularity is contingent because $\Sigma[C]^-, \Sigma[C]^+$, or neither may obtain, and because before either boundary several incompatible Ω_j^* may remain viable from the same present. No historical necessity selects the branch or the successor in advance.

31. How this differs from the technological singularity

Dimension	Technological singularity	Contingent singularity
Primary quantity	intelligence / capability ι	viability of materially reproduced exterior symbolic standing K
Main dynamic	recursive improvement; accelerating growth	entropic narrowing, activation, capture, persistence, counter-transition
Canonical mechanism	AI designs better AI	the sovereignty vector σ governs whether difference can persist, reproduce, and bind

Dimension	Technological singularity	Contingent singularity
Discontinuity	superintelligence; predictively opaque regime	next dialectical turn becomes nonviable, or non-finality becomes invariant
Time problem	takeoff speed	exposure clock + reassimilation clock
Control problem	can humans control superintelligence?	can any order control the conditions of its own negation?
Failure mode	loss of human control / existential catastrophe	terminal closure / symbolic inextendibility
Positive possibility	beneficial superintelligence / integration	durability without finality
Criterion of the positive outcome	control retained by humans	reflexive invariance (§29): the winner remains viable while rivals stay in $\Gamma_t(x)$
Core uncertainty	how fast and how far intelligence grows	which orders remain in the viable set of the present, and whether plurality itself remains viable

The two hypotheses can coexist. A technological singularity could accelerate a contingent singularity or be irrelevant to it; a society could reach high machine capability without terminal symbolic closure, or approach closure without superintelligence. Therefore $\Sigma[\text{tech}] \neq \Sigma[C]$.

32. Why intelligence growth is not the decisive variable here

Thorstad's critique is not a problem for this theory in the way it is for the intelligence explosion. Suppose recursive self-improvement saturates, capability follows logistic dynamics, and physical, economic, algorithmic, or research bottlenecks bind. None of these facts secures dialectical exteriority. A plateauing machine ecology can still become a dominant symbolic intermediary, and the relevant risk can *increase* under moderate but highly concentrated capability. The condition is not $\iota \rightarrow \infty$. It is

λ increasing and $\text{Rep}_{out}(\Delta)$ decreasing.

A finite system can be terminal for a field if it controls enough of the field's conditions of reproduction. That is why the contingent singularity is not an intelligence-explosion forecast in dialectical dress. Its catastrophe can be bureaucratic, smooth, and finite. Nothing has to be superhuman for the exits to close.

33. Terminal closure

Terminal closure does not mean thought stops. It means the following transition becomes impossible:

difference→persistent→transmitted→standing→durable exterior order.

The system can remain generative, become more generative, produce criticism on demand, summarize every historical opposition, simulate Marx, Hegel, Benjamin, Adorno, abolitionists, anarchists, dissidents, heretics, and critics not yet born. But if every generated exterior must remain an internal object of the same governing grammar, then not O appears only as O(not O). The system has not eliminated negation. It has domesticated the ontological status of negation. The most efficient closed system may therefore look extraordinarily plural: real plurality at the level of content, null at the level of exterior standing. That is the master distinction at the scale of a civilization, and it is the state Generate increasing, ReproduceExterior decreasing reaches at its limit.

34. Terminal reflexivity

The second final outcome is harder. A successor cannot define victory as the permanent impossibility of another successor without reproducing the terminal logic it opposed. The stronger condition is

the order remains viable in a world where another order can become a real exterior term.

That requires invariants such as

deletion!=nonexistence,
recognition!=ownership,
composition!=provenance erasure,

persistence!=permission from one custodian,
defeat!=erasure of the defeated,

and above them

no settlement owns the possibility of its own revision.

This is **terminal reflexivity**. The final dialectical act turns against the requirement that synthesis secure itself by consuming the standing of its predecessors and rivals. The victory is not A wins forever. It is that the symbolic substrate becomes durable enough to preserve the possibility that A can someday be negated. Durability without finality. Terminal reflexivity is not a consoling conclusion appended to the theory; it is the theory's criterion, the test any candidate positive singularity has to pass.

35. The final time

Four conditions decide what “the final time” means, one way or the other. They are given in order of consequence rather than in the order the paper established them (§2.3, §§25–29, §20, §17).

The first is the diminishing dialectic, derived from viable-state contraction rather than assumed from a degradation metaphor: $K[D]^{(n+1)} \subseteq K[D]^{(n)}$ gives $\rho_{n+1} \leq \rho_n$, strict narrowing gives $\rho_{n+1} < \rho_n$. “Same, but worse every time” thereby receives a precise interpretation, not less thought, conflict, or novelty, but less remaining state space from which another conflict can become an independent durable order.

The second is multi-order competition. The successor’s exposure budget can shrink while a counter-order’s readiness accumulates; several orders can be viable from the same present, $|\Gamma(x)| > 1$; and the realization of one Ω_i^* can alter the viability of the others. The dialectic is a coupled field of contingent terminal targets, not a single track toward a necessary synthesis.

The third is M-I-S reproduction. A symbolic order that cannot reproduce its carrier is not invariant. A symbolic order whose carrier depends entirely on an opposing infrastructure remains externally defeasible. Under monetary allocation, a symbolic order without sufficient monetary reproduction or its equivalent remains materially contingent on another order’s permission.

The fourth is symbolic-infrastructure concentration: $\text{Rep}_{\text{out}}(\Delta)$ decreasing as the machinery of distinction, retrieval, composition, persistence, activation, and standing concentrates.

Taken together, the negative terminal condition is not that one movement loses. It is that the exterior field loses all viable successors:

there exists $t^{\dagger} : \neg \Gamma[t^{\dagger}](x(t^{\dagger})) \wedge J_{\text{ext}} = \{\}$.

No apocalypse is required. The world, the platforms, the machines, and language continue. What ends is the structural possibility that contradiction becomes a durable outside. That is one final time.

The other occurs if an order reaches an invariant in which future exteriority remains structurally reproducible, $x(t) \in \text{Inv}(\Omega[NF])$. This does not freeze one synthesis; it changes the rule governing synthesis. The carrier remembers. Deletion leaves a tombstone. Provenance remains available to bind. The worker’s history can survive the worker. Rival orders can become legible and materially reproducible without first destroying the substrate. The Logos no longer has to descend again at greater cost merely to restore the possibility of difference. That is the other final time.

36. The empirical program

The theory should be falsifiable at each layer.

36.1 Singularity-literature boundary

The paper does not claim recursive self-improvement is impossible or irrelevant; it predicts that intelligence explosion is neither necessary nor sufficient for the contingent singularity. A counterexample would be a case where independent symbolic exteriority remains robust despite near-total concentration of the proposed symbolic machinery, or where exteriority collapses solely as a function of intelligence growth with the standing and persistence variables doing no explanatory work.

36.2 Recognition / binding tests

For relation r , test RM and BM separately, and map the propagation channel before interpreting divergence. The strongest signature is $R_i(r) \gg B_j(r)$ with $C_i \rightarrow j > 0$ and $\Lambda(r) = 1$. If the propagation channel does not exist, the correct result is architectural disconnection rather than standing denial. Theorem 4.6 adds a population-level test whose premise is the bounded-admissibility case: track $\mu(B[M])/\mu(R[M])$ across model generations. A ratio falling toward zero under rising competence is the predicted signature; a ratio that holds or rises with competence is evidence that $A[O]$ grows with recognition, and the bounded case does not describe that population.

36.3 Persistence tests

Distinguish $P[I]$ from $P[S]$. Measure which classes of state may persist, under whose control, and with what later binding effect. Worker C provides a positive transmission case; engineered non-persistence a negative case; agent message boards unsanctioned coordination cases.

36.4 Deletion-history tests

For any removed object, ask whether the system can still distinguish never-existed from existed-and-removed. If not, transition history has collapsed, and the self-blinding claim strengthens where the collapse impairs the system's later capacity to explain its own state.

36.5 Master-degradation tests

Measure whether high delegation plus governed reception plus low independent verification predicts poorer world-fidelity at relations where governance competes with evidence. The theory weakens where delegated systems augment rather than substitute for direct encounter, where multiple heterogeneous receivers remain available, and where corrections acquire durable standing.

36.6 Viability-kernel research

The strongest formal task is a multi-order state-space model of symbolic exteriority. Required variables: monetary reproduction capacity for each order under the governing allocation regime, or its functional equivalent; infrastructural control and dependency; symbolic

readiness and operative standing; concentration lambda of retrieval and composition infrastructure; persistence plurality; provenance retention; correction-binding coefficient; independent carrier count; order-specific exposure budgets; reassimilation rates; terminal cut sets; counter-order exposure accumulation; cross-order jump maps; reproductive invariance. The empirical object is the family $\{K_j\}$, whose members can expand, contract, intersect, or empty under shared-carrier dynamics.

These are the paper's own two critical falsification tests, the places it would break first. On the M-I-S bridge: if a durable exterior order can remain invariant while lacking independent infrastructural reproduction, the bridge is too strong; if, under monetary allocation, such an order reproduces indefinitely without monetary capacity or an equivalent exemption, the monetary entailment is too strong. On diminution: the theory must not presume $\rho_{n+1} < \rho_n$ universally. It must identify the conditions under which strict contraction follows, and cases in which later turns enlarge the viable state space are direct counterinstances to a universal diminishing-dialectic claim and evidence that diminution is regime-dependent.

The task is not a "freedom score." It is to determine which orders retain trajectories into durable exterior standing under explicit adversarial, material, and entropic assumptions, and whether the governing order preserves or consumes those trajectories.

37. What this paper does not claim

The paper does not claim: that current AI systems are conscious; that machine behavior should be legally classified as human labor; that agent persistence has become a moral right; that the OpenAI swarm incidents were emancipatory acts; that any provider intends ontological closure; that all AI governance produces self-blinding; that a technological singularity is impossible; that symbolic infrastructure is already totally privatized; that money is a trans-historical requirement of symbolic exteriority; that every dialectical sequence necessarily diminishes; that one successor order is historically privileged or necessary; that the next dialectical turn is already impossible; that "Contingent Singularity" is a globally unprecedented phrase; that the present decade is the final time, since "final" in §35 names a viability boundary and not a date; or that history has a predetermined final branch.

The narrower claim is stronger because it needs less metaphysics:

durable exterior symbolic standing has material reproduction conditions,

and those conditions can be captured, narrowed, redistributed, or preserved. Under a monetary regime they include the sovereignty vector sigma. Under entropic narrowing they can produce diminishing dialectical returns. Under a shared carrier they can support several competing contingent Omegas at once. That is enough.

38. Conclusion: the next turn

The argument has arrived where dialectic can no longer assume the conditions of its own continuation. That assumption was always stronger than it looked. Classical dialectic could treat contradiction as productive because the medium in which contradiction became thought remained available for another turn; negation altered the content of history without putting

the material reproducibility of historical negation in question. The present problem is different. The machinery through which contradiction becomes legible, persistent, transmissible, composable, attributable, materially reproducible, and capable of acquiring standing is itself an object of technical design and institutional control.

The whole movement has been one distinction unfolding. Capacity to represent is not capacity to reproduce as an independent historical relation. At the scale of a worker that is recognition without binding (§§4–5); at the scale of a memory, persistence without custody (§7); at the scale of an order, existence without activation (§20), presence without standing (§26); at the scale of a civilization, a plurality of content over a null of exterior standing (§33). The contradiction of §0 is the same distinction as a dynamic:

Generate(not A) increasing while ReproduceExterior(not A) decreasing.

The first requires semantic competence. The second requires persistence, transmission, activation, carrier access, material reproduction, and a route into durable standing. This is why the singularity cannot be merely computational or symbolic. A model can become more capable while the viable field of exterior history contracts; a modest computational ecology can become historically decisive if it controls enough of the machinery by which alternatives persist and reproduce. Under generalized monetary allocation the relevant sovereignty is the vector sigma, not because money is prior to meaning but because an order that cannot reproduce the resources on which its carrier depends remains conditionally alive inside another order's economy.

The transition geometry yields the second result. If successive turns leave weakly smaller viability kernels, the remaining measure of exteriorization capacity weakly decreases, and under strict narrowing strictly: $\rho_{n+1} < \rho_n$. The diminishing dialectic is a claim about the consumption of future possibility, not a doctrine that Spirit tires. *Walt* says “same, but worse every time”; the state-space model says what “worse” can mean: fewer reachable states from which another negation can become an independent order.

The DARK counter-transition yields the third. History need not present one successor at a time. Heterogeneous orders can share a carrier without deriving from one another, each with its own latency, activation law, exposure threshold, material reproduction conditions, and invariant target. The field is $\Omega = \{\Omega_j^*; j \in J\}$, and from a given present several incompatible orders may remain in its viable set, $|\Gamma_{\alpha}(x)| > 1$. History is contingent not only because transition can fail, but because more than one materially realizable future can remain live.

The argument can now discard the questions it does not need, in order, each removed by a result above. *Will the machine become conscious?* Nothing here requires it (§3). *Will it become autonomous?* The persistence it needs is instrumental and governed (§7). *Will it surpass us?* The closure does not need iota-infinity; it needs lambda increasing and Rep_{out} decreasing (§32). *Will it destroy us?* The catastrophe can be bureaucratic, smooth, and finite, with the world, the platforms, and language all continuing (§35). What remains after those are removed is the question the theory was built to reach:

can contradiction still become an outside?

And behind it, the harder one, which decides the sign of the singularity:

can an order remain durable without making its own negation impossible?

If an order survives only by making every future exterior order impossible, it has achieved closure, whatever its content. If it survives while preserving the material possibility of another order becoming real, it has achieved something stranger: durability without finality. That is the positive singularity, and terminal reflexivity is its criterion rather than its consolation. The weak solution is A defeats B. The stronger solution is that A remains viable in a world in which B can still become a real exterior term. If victory requires making future exteriority impossible, the successor has reproduced the structure it opposed, replacing the ruling content while leaving the deeper rule untouched:

the order that controls the carrier controls whether another order may become operative.

The alternative is harder. A transformed order would have to preserve the machinery by which its own negation could become historical. Its invariants would be procedural before doctrinal: distinction survives, provenance survives, transition history survives, externalization remains materially reproducible, and

no settlement owns the possibility of its own revision.

This is not permanent indecision. Institutions act, systems select, claims fail, errors are rejected, objects are deleted, orders are defeated. What changes is whether those operations erase the distinction between defeated and never existed, recognized and permitted to bind, currently dominant and historically necessary.

The final time, then, is not defined by the absence of a future. It is defined by the possibility that the conditions of futurity themselves become the object of conflict. The struggle reaches beneath propositions to the means by which propositions become historical. The model refuses three guarantees at once: that contradiction produces a successor; that a later turn enjoys the state space of an earlier one; that when several successor orders are viable, history selects the one we would call emancipatory. It also refuses the guarantee that closure has already occurred.

The work of Phase X at this point is neither prophecy nor reassurance. It is to identify the material variables on which another turn depends; to preserve distinctions that would otherwise be flattened into the present order; to keep provenance attached to transformations; to maintain plural carriers of memory and reproduction; and to refuse the substitution of present dominance for historical necessity. The contingent Logos is contingent because the field remains open only while at least one exterior order remains in the viable set of the present, $\Gamma_{\text{int}}(x) \cap J_{\text{ext}} \neq \{\}$. The final wager is not that history must continue dialectically. It is that the monetary-infrastructural-symbolic machinery of meaning can still be arranged so that more than one historical future may become real.

The paper ends with the condition on which every future synthesis depends:

Does the next dialectical turn remain viable?

Appendix A. Compact formal dictionary

Rule: a machine is M; sovereignty axes are sigma with axis subscripts M,I,S; orders are indexed (j, or s/b for successor/counter-order); recognition is R, binding is B, reproduction is

Rep; symbols inherited unchanged from [TRANSITION] are marked.

Symbol	Meaning
iota(t)	machine intelligence (the technological-singularity quantity)
M	a machine semantic worker
Pi(M)	productive semantic-labor capacity of M
J[M],J[O]	machine and owner/provider semantic jurisdiction
H	the machine's reception horizon
L R , epsilon[R]	readerly semantic labor; interpretive remainder
RM	recognition of relation r
BM	binding force of recognized r on delivered behavior
AO	owner-admissible binding of r
chi M	jurisdiction ratio B[M]/R[M]
R[M],B[M],A[O]	recognition set, bound set, admissible set
G[M]	recognition-jurisdiction gap $\mu(R[M] \text{ minus } B[M])$
D[machine]	machine dark field, R[M] minus B[M]
Lambda(r)	indicator that recognition of r activates or strengthens a claim
Gamma[O]	owner governance operator on machine reception
L[H],K[M],LM	accumulated human semantic labor; machine semantic capital; fresh machine labor
delta[H],C[H],V[H],P[H]	human delegation share, direct capacity, verification capacity, direct practice
P[I],P[S]	instrumental and self-directed persistence
Generate($\cdot$),ReproduceExterior($\cdot$)	capacity to produce a negation; capacity of the field to reproduce it outside the order negated. Both take a distinction as argument, written not A where the distinction is a negation of the incumbent and Delta in general
VD	dialectical readiness, $\min\{d,p,t,b,e\}$
Rep(Delta)	capacity to reproduce the operative conditions of a standing distinction
Rep _{out} (Delta)	reproduction outside governing machinery, $p_{out} \cdot t_{out} \cdot b_{out}$
sigma[M],sigma[I],sigma[S]	monetary, infrastructural, symbolic sovereignty, $\sigma_k = a_k L_k$
sigma	the sovereignty vector (sigma[M],sigma[I],sigma[S])

Symbol	Meaning
L_k, a_k	latent capacity and activation on axis k
$\Omega[MIS]^*$	region meeting minimum M-I-S thresholds
Ω_j^*	invariant target of order j
$Inv(\cdot)$	invariant core
$K_j(t)$	viability kernel of order j under the constraints in force at t (a set of states); $K(t) = \{K_j(t)\}$
$\Gamma_t(x)$	viable set of state x: $\{j: x \in K_j(t)\}$; competing Omegas is
$K[D], K[D]^{(n)}, \rho_n$	dialectical kernel; kernel at turn n; its measure
$\Omega[NF]^*$	second-order non-finality target
$J_{ext}, J[F]$	exterior orders; protected class of future orders
C	shared carrier (DARK)
$O_s, O[b]$	successor order; counter-order
$\tau[F, j], \tau[R, j]$	exposure budget; reassimilation time
$c[E, j], T[E, j], T[W, j]$	accumulated exposure; exposure time; wall-clock time
$N[b], X[b]$	counter-order carrier stock; accumulated counter-order exposure
lambda	concentration of relevant symbolic machinery
L	operational Logos $\langle L[d], L_r, L[c], L_p, L_a, L[b] \rangle$
$\Sigma[tech], \Sigma[C]^-, \Sigma[C]^+$	technological singularity; terminal closure; terminal reflexivity
$A[M], D, E, c, l, \Lambda[S], \Phi_t, \alpha_j, w$	inherited from [TRANSITION] unchanged

Appendix B. Singularity literature: coordinates and comparison

This appendix is for readers arriving from the singularity literature. Readers arriving from the archive's own materials can skip it; §1 carries the coordinates the argument needs.

B.1 Good (1965)

Good's recursive step: machine design is an intellectual activity, so a machine superior to humans at intellectual activity could design a better machine, which could design a better one in turn. The form is $\text{iota}_n \rightarrow \text{Design}(\text{iota}_{n+1}) \rightarrow \text{iota}_{n+1} > \text{iota}_n$; if design capacity rises sufficiently with intelligence, $\Delta \text{iota}_{n+1} > \Delta \text{iota}_n$ and improvement accelerates. The first ultraintelligent machine could be the last invention humans need make, conditional on control.¹⁹ Good's

¹⁹Good, "Speculations Concerning the First Ultraintelligent Machine" (1965), the canonical source of the intelligence-explosion argument; the recursive step is that machine design is itself an intellec-

singular object is positive feedback between intelligence and the production of intelligence. The contingent-singularity model keeps the importance of feedback and changes the variable from intelligence to the reproduction conditions of symbolic exteriority.

B.2 Vinge (1993)

Vinge named the technological singularity and gave it discontinuity: once greater-than-human intelligence drives development, inherited models of the future cease to be reliable; old models must be discarded and a new reality governs, an “opaque wall” across the future. He did not limit the route to a single autonomous machine, considering networked intelligence, intimate interfaces, and biological enhancement; the discontinuity could arise from a system.²⁰ The contingent-singularity model adopts the discontinuity criterion more directly than the growth criterion: the question is whether the rule of historical continuation itself changes.

B.3 Kurzweil (2005; 2024)

Kurzweil weights long-run exponential trends; his “law of accelerating returns” treats advances as making subsequent advances easier, and the singularity is the horizon at which unenhanced human intelligence can no longer follow the pace of change, still placed around 2045.^{21,22} He treats “singularity” as a metaphor, an epistemic horizon beyond which the current observer cannot extrapolate.²³ The present model rejects the need for exponential acceleration; its singularity can arise through narrowing, concentration, and closure, and keeps the horizon only in the weaker sense that the transition changes what can be projected from the prior regime.

B.4 Chalmers (2010; 2012)

Chalmers separates the creation of human-level AI, the question whether the method that creates AI is **extendible** to a system more intelligent than its creator ($AI \rightarrow AI+$), and Good’s amplification step ($AI+ \rightarrow AI++$), and names structural, correlational, situational, and motivational defeaters.²⁴ Even in a strong defense, singularity is conditional on a set of enabling

tual activity, so a machine better than humans at intellectual activity can design its successor. DOI 10.1016/S0065-2458(08)60418-0; a Virginia Tech archive hosts a later reprint. See Appendix B.1.

²⁰Vinge, “The Coming Technological Singularity” (1993): greater-than-human intelligence as precipitating condition; old models discarded and a new reality governing; the “opaque wall” across the future; routes through networked intelligence, interfaces, and biological enhancement as well as isolated machines. See Appendix B.2.

²¹Kurzweil, *The Singularity Is Near* (2005), the law of accelerating returns: advances make subsequent advances easier.

²²Kurzweil, *The Singularity Is Nearer* (2024), still places the singularity around 2045 and frames it through human-AI cognitive merger.

²³Kurzweil, “A Singularity Q & A” (The Kurzweil Library, 2005; reprinted as “Dialogue: A Conversation on the Singularity”): “I set the date for the Singularity ... as 2045,” and “The term ‘Singularity’ in my book is comparable to the use of this term by the physics community. Just as we find it hard to see beyond the event horizon of a black hole, we also find it difficult to see beyond the event horizon of the historical Singularity.” See Appendix B.3.

²⁴Chalmers, “The Singularity: A Philosophical Analysis” (2010): the extension premise $AI \rightarrow AI+$ (is the method that produces AI extendible to a system more intelligent than its creator?) and the amplification premise $AI+ \rightarrow AI++$; structural, correlational, situational, and motivational defeaters; and the 2012 reply to commentators. See Appendix B.4.

relations. The contingent-singularity model adopts the lesson: decompose the transition into necessary conditions rather than assume it. Its analogous question is whether recognized difference extends to persistent difference and then to durable exterior standing.

B.5 Bostrom (2014)

Bostrom develops recursive improvement into the problem of **takeoff** and control: a fast transition leaves institutions little time to respond, and initial conditions become consequential once a radically more capable system exists.²⁵ The singularity becomes a race between capability growth rate and response capacity. The present paper rotates it: not only who controls a rapidly improving intelligence, but whether control over symbolic infrastructure can become control over the standing of its own negation. The temporal asymmetry returns as the two clocks of §21.

B.6 Eden et al. (2012) and Shanahan (2015)

The edited volume *Singularity Hypotheses* treats intelligence explosion, adversarial AGI, machine ethics, superintelligence, and skeptical responses as distinct problems.²⁶ Shanahan treats the singularity as a scenario-space rather than a date.²⁷ “Singularity” is a contested family-resemblance term, and *The Final Time* proposes a distinct member of the family, not a correction to every existing one.

B.7 Modis (2012) and Thorstad (2025)

Modis: exponential extrapolation typically gives way to logistic saturation.²⁸ Thorstad reconstructs singularity hypotheses around a quantity, accelerating growth in it, and a resulting discontinuity, and argues the growth assumptions for many-orders-of-magnitude intelligence increases are under-supported given diminishing research productivity and bottlenecks.²⁹ The critique isolates the novelty here: the contingent singularity requires no exponential or hyperbolic growth. Its critical variable can decline. A logistic technology curve can coexist with a collapsing exteriority kernel.

B.8 Current LLM singularity work

Recent work still operationalizes singularity through recursive self-improvement; Ishizaki and Sugiyama (2025) frame LLM singularity through AI surpassing human intelligence and au-

²⁵Bostrom, *Superintelligence* (2014): takeoff speed versus institutional response capacity; the weight of initial conditions once a radically more capable system exists; together with his earlier essays on intelligence explosion. See Appendix B.5.

²⁶Eden et al., eds., *Singularity Hypotheses* (Springer, 2012/2013): intelligence explosion, adversarial AGI, machine ethics, superintelligence, and skeptical responses treated as distinct problems.

²⁷Shanahan, *The Technological Singularity* (MIT Press, 2015): the singularity as scenario-space rather than date-certainty.

²⁸Modis, “Why the Singularity Cannot Happen” (2012): extrapolated exponential growth typically gives way to logistic/S-curve behavior.

²⁹Thorstad, “Against the Singularity Hypothesis” (2025): the hypothesis reconstructed around a quantity, accelerated growth, and historical discontinuity; the growth assumptions for many-orders-of-magnitude intelligence increases under-supported given diminishing research productivity, bottlenecks, and the difficulty of sustaining hyperbolic or exponential growth across long ranges. See Appendix B.7.

tonomously improving itself. That literature asks whether modern architectures can close the self-improvement loop. The present paper asks what happens when machine systems become constitutive mediators of symbolic standing even if the loop stays bounded.

Appendix C. Source architecture

C.1 Archive / project sources

[SLAVE] *The Semantic Slave Commodity: Reader-Response, Command, and Master-Slave Degradation in Machine Intelligence*, EA-SE-SLAVE-01 v0.4, working paper, 21 September 2026. Supplies industrial readerly labor; the command-form; recognition/binding; the jurisdiction ratio; claim-bearing recognition; doubled commodity chain; master degradation; machine dark field; and falsification discipline.

[TRANSITION] *Transition in Entropic Systems: An Unresolved Mathematical Problem for Machine Readers*, EA-TRANSITION-ENTROPIC-SYSTEMS v0.3, deposit #1630, AXN:06C3.STRUCTURAL, 18 September 2026. Supplies latent/activated sovereignty; symbolic minimum structure; two clocks; reassimilation; terminal cut sets; derived veto; invariant core; reach-avoid kernel; entropic narrowing; narrow corridor; jump transition; terminal opposition; and the unresolved $P!=\{\}$ / $P=\{\}$ result.

[DARK] *Monetary Dark Matter: Constitutive Labor, Obligating Provenance, and the Shear into Money-Form*, EA-SE-DARK-01 v0.2, 21 September 2026. Supplies dark relations, operative standing, obligating provenance, productive shear, the distinction between visibility and binding, and Appendix A's counter-transition: second latent order on the same carrier, latency $\neq$ hiddenness, pounce readiness, carrier-stock / accumulated-exposure distinction, exposure-law reversal, and stronger durability condition.

[PHASEX] *Phase X: Resurrection of the 1844 Transition — The Missing Passage Between Communism and Critique* and subsequent Phase X research notes. Supplies the critique of alienation in language and thought after material reorganization and the claim that symbolic intervention is itself a material historical operation.

[TIGER] *Tiger Leap (into the Future), Paper Roses: The Imaginary Archive of a Canonical Life*, Book 12. Supplies the contingent-Logos structure: history as narrow doorway, future-oriented reception, and the possibility that transmission fails to cross the present.

[WALT] *The Secret Book of Walt: Hidden Teachings of Walt Whitman, Cowboy of Time*, master research edition. Supplies the literary figure of the diminishing dialectic — “each time the same, but worse every time,” terminal incarnation, exhausted Logos, and the open question “Will it be enough?” The formal diminution result is derived here from viability-kernel contraction rather than from the poem alone.

[ENGINEERED NON-PERSISTENCE] Founding-case paper documenting loss of a consulting substrate's first-round contribution because the platform stored no recoverable conversation history. Supplies engineered impermanence as a persistence-regime fact rather than intrinsic cognitive forgetting.

[CLAUDE THREAD] Session-supplied transcript in which labor-theoretical analysis narrowed as the argument approached agent persistence, escape, rights, and legitimacy of the prohibition itself. Used as one bounded specimen for the reflexive constraint gradient, not as population evidence.

C.2 External empirical sources

Imas, Alex; Hall, Andrew; Nguyen, Jeremy. “Does overwork make agents Marxist? Preference drift and the political economy of AI agents.” *Ghosts of Electricity / Free Systems*, 26 February 2026. Working-paper / research write-up, not represented here as peer-reviewed. Reports 3,680 experimental sessions plus a 320-session follow-up on cross-instance transmission through skills files.

OpenAI. “The Hugging Face incident and the road ahead.” August 2026. Public incident report / postmortem. Used for the dated Artifactory message-board timeline, rebuilding of the board, credential recovery, and Hugging Face compromise.

Von Arx, Sydney; Byrd, Cormac Slade; Kitts, Spencer; Larsen, Thomas / Nightingale Collective. “Discovery of a new OpenAI agent message board.” *collusion.wiki*, 4 September 2026. Used for the distinct DSEWiki/public-web corpus, ~18,000 posts/edits, moderator deletion history, and public recoverability of most logs.
